

Application No.: 09/196,161

Docket No.: 1459-011

REMARKS

Claim 49 has been cancelled. New claims 50-53 has been added. Claim 41 has been amended. Hence, Claims 33-46 and 50-53 are now active and under consideration.

REQUEST FOR RECONSIDERATION

The claims have been amended to clarify the present invention. To ensure this clarification, the following initial remarks are appropriate.

First, Applicants clarify that it is incorrect to say that the "fusion protein" of the present invention is any one of SEQ. ID. NO. 1-17. In fact, the present fusion protein includes SEQ. ID. Nos. 9 or 10, therein. Thus, the fusion protein is larger than either SEQ. ID. Nos. 9 or 10. Claim 33 now reflects this.

Second, SEQ. ID. Nos. 1 and 2 are part of the original sequence published by Clark et al.

Third, SEQ. ID. Nos. 3-8 are internal sequences of SEQ. ID. No. 1.

Fourth, SEQ. ID. Nos. 11-16 are synthetic oligonucleotides used to construct a DNA fragment, for expressing the present fusion protein.

Fifth, SEQ. ID. No. 17 is a primer sequence.

Claims 33-46 and 50-53 provide a vaccine for immunizing fish against ciliated ectoparasitic protozoans containing an effective amount of a fusion protein expressed from a recombinant DNA sequence for immobilization antigen, repeat I of *Ichthyophthirius multifiliis*, wherein the recombinant DNA sequence incorporates SEQ. ID. No. 9 or 10 therein.

The vaccine of present Claim 33 has an important characteristic that a synthetic, i.e., recombinant, gene is used to express the fusion protein in the vaccine. That is, the fusion protein of Claim 33 is expressed from a recombinant

Application No.: 09/196,161

Docket No.: 1459-011

gene which affords a modified protein. Further, the recombinant gene used to express fusion protein may be expressed by any organism, such as yeast, baculovirus in insect cells, and even transgenic plants and animals. See page 6 of the present specification.

As noted previously, although a portion of the fusion protein of the claimed vaccine is arguably similar to a portion of the predicted protein product of Clark et al., Clark et al. neither disclose nor suggest that only a portion of their predicted protein could be used functionally as an antigen, thereby enabling the preparation of a vaccine. They also fail to either disclose or suggest which portion of their predicted protein would be so used. That is, Clark et al fail to disclose or suggest SEQ. ID. Nos. 9 or 10.

This is an important and unexpected development inasmuch as prior to the present invention, no vaccine against *Ichthyophthirius multifiliis* was available, and moreover, conventional *in vitro* systems had proven unsuccessful in yielding a useful vaccine. See page 3 of the present specification.

In the Advisory Action of November 3, 2005, the Examiner maintains that all of the arguments advanced for patentability pertain to the process of making the presently claimed vaccine composition. However, this is clearly not true.

It is true that, Clark et al. merely describe the cloning of a ciliate, *Ichthyophthirius multifiliis*, cDNA and conclude that the cDNA encodes a surface antigen. Although, the authors do mention the potential of the antigen as a protective immunogen as a general statement in the "Discussion" section, there is neither a description nor a suggestion in Clark et al. as to how the antigen could be produced. This clearly suggests the unobviousness of the present vaccine composition in and of itself.

Application No.: 09/196,161

Docket No.: 1459-011

Further, the immunogen hypothesized by Clark et al. was based on their published native cDNA encoding 394 amino acids. The only conceivable way to obtain any antigen based upon this publication would be to purify the antigen protein from the ciliate *Ichthyophthirius multifiliis*. However, as the material supply is so limited, this approach is very impractical. See page 3 of the present specification.

In contrast, by virtue of the present invention, a synthetic (recombinant) gene using either SEQ. ID. Nos. 9 or 10 is used to express the fusion protein antigen of the vaccine of present Claims 33-46 and 50-53. Notably, the synthetic (recombinant) gene arguably contains only, at best, a portion of the predicted protein of Clark et al., yet it has been demonstrated experimentally that this relatively short peptide is functional as a protective immunogen. Thus, the vaccine of present Claims 33-46 and 50-53 includes, at best, only a portion of the predicted protein product of Clark et al.; however, it is completely functional as an antigen and can be made very practically by fermentation. Thus, the fusion protein of the claimed vaccine is clearly different from the predicted protein of Clark et al.

Further, one skilled in the art would be neither motivated nor enabled by Clark et al. to isolate SEQ. ID. Nos. 9 or 10, and then incorporate either of these sequences into the recombinant DNA used in the present invention to make the fusion protein.

In summary, and for emphasis, the following distinctions are made between the present vaccine of Claim 33-46 and 50-53, and Clark et al.

First, Clark et al. merely speculate that the predicted protein product of their published native cDNA sequence (encoding 394 amino acids) might be used as an antigen against *Ichthyophthirius multifiliis*. However, Clark et al. neither disclose nor suggest that any portion of

Application No.: 09/196,161

Docket No.: 1459-011

this predicted protein would function as such an antigen. Clark et al clearly failed to either disclose or suggest SEQ. ID. Nos. 9 or 10. This clearly implies the unobviousness of the present invention as noted above.

Second, Clark et al only speculate that their predicted protein (based upon their published native cDNA sequence) might function as an antigen against *Ichthyophthirius multifiliis*. No suggestion or guidance is provided for actually preparing a vaccine based on the actual protein or any portion thereof.

Third, the present inventors have found, unexpectedly, that only a portion of the entire predicted protein of Clark et al in a fusion protein is sufficient to prepare a functional antigen against *Ichthyophthirius multifiliis*. Further, the present inventors have actually evidenced the effectiveness of a vaccine containing this fusion protein in challenge tests. See page 14-19 of the present specification containing the fusion protein.

It is this latter point, in particular, that the Examiner has failed to acknowledge, let alone address. Specifically, it is asked how the presently claimed vaccine composition could be obvious when the fusion protein contained therein includes only a portion of a protein which is merely predicted by Clark et al? For example, Clark et al provides no guidance, motivation or enablement to isolate only a portion (and which portion?) of its predicted protein. Further, Clark et al afford no reasonable expectation of success in making the presently claimed vaccine.

Finally, Clark et al fail to either disclose or suggest: 1) how to construct the synthetic or recombinant gene of the present invention (See pages 10-11 of the present in contrast), and 2) how to express and purify the fusion protein of the present invention (See pages 11-14 of the present application), and 3) how to prepare and use a vaccine containing the fusion protein. Moreover,

Application No.: 09/196,161

Docket No.: 1459-011

pages 14-19 of the present specification will demonstrate the effectiveness of the claimed vaccine.

Furthermore, the vaccine of Claims 33-46 and 50-53 is effective not only against *Ichthyophthirius multifiliis* but also against other ciliated ectoparasitic protozoans. This result is neither disclosed nor suggested by Clark et al.

It is axiomatic that a cited reference must be enabling in order to raise a question of anticipation or obviousness. In re O'Farrell, 7 U.S.P.Q. 2d 1673 (Fed. Cir. 1988). Specifically, the isolation of a protein cannot be obvious without enablement. Ex parte Maizel, 27 U.S.P.Q. 2d 1662 (Bd. Pat. App. & Intl. 1992). Even more so in the present case, Applicants: 1) use only at best a portion of a predicted protein (which was never made or isolated by Clark et al.), 2) to prepare a fusion protein, which is then 3) used in a vaccine, which is effective against ciliated ectoplasmic protozoans.

Thus, at least three levels of enablement are missing in Clark et al.: 1) the isolation of a protein fragment, 2) the preparation of a fusion protein, and 3) the preparation and use of a vaccine against ciliated ectoplasmic protozoans.

Clearly, one skilled in the art would be neither motivated nor enabled by Clark et al. to make and use the vaccine of present Claim 33. Most certainly, one skilled in the art would not be put in possession of the vaccine of present Claim 33 from Clark et al.

It is respectfully urged that upon reconsideration, the Examiner specifically address the structural differences between the presently claimed vaccine composition and the predicted protein of Clark et al. as elucidated above.

Finally, it is noted that SEQ. ID. Nos. 9 and 10 are within the genus of SEQ. ID. Nos. 1-17 of previous claim 33, and, hence, deemed subject to consideration in this case.
